Background and context

Image uploading right now involves capturing an image, saving it to somewhere, finding it, and uploading it through a service (Imgur, photobucket, etc...). We propose a new process:

1. One time setup of options (hotkeys, where to upload, how to upload, ...)
2. Hotkey activated chain of events (defined by user)

Functions	Effects
Image Uploading	Ability to upload image to variety of hosts along with options for naming, captions, albums, etc.
Image Capturing of predefined shapes	Ability to capture variety of images from screen by predefined shapes
Text Sharing	Ability to share text (like links) via social media or clipboard
QR Code Generation	Conversion of plain text and/or links into scannable QR codes
Image Editing	Snapchat-esque scribbling/captions
User-Designated workflows	User decides how to capture and what to capture, what to do after capturing, and chooses various sharing options

Questions
- Do you (as a user) want to select options after capturing an image, or before?
- Would you prefer anonymous hosting or account specific hosting?
- How often do you want to screenshot your screen and share the pictures with others?
